FILE COVERS 1907 - 1 Feb 2002  VOL 136 ISS 6
FILE LAST UPDATED: 30 Jan 2002  (20020130/ED)

 This file contains CAS Registry Numbers for easy and accurate
 substance identification.

CAS roles have been modified effective December 16, 2001. Please
check your SDI profiles to see if they need to be revised. For
information on CAS roles, enter HELP ROLES at an arrow prompt or use
the CAS Roles thesaurus (/RL field) in this file.

The P indicator for Preparations was not generated for all of the
CAS Registry Numbers that were added to the CAS files between 12/27/01
and 1/23/02.  As of 1/23/02, the situation has been resolved.  Searches
and/or SDIs in the H/Z/CA/CAplus files incorporating CAS Registry
Numbers with the P indicator executed between 12/27/01 and 1/23/02 may
be incomplete.  See the NEWS message on this topic for more information.

AB The present invention relates to **chimeric polypeptides** in which a **serum albumin** protein has been altered to include one or more biol. active **heterologous peptide** sequences. The **chimeric polypeptides** may exhibit therapeutic activity related to the **heterologous peptide** sequences coupled with the improved serum half-lives derived from the **serum albumin** protein fragments. **Heterologous peptide** sequences may be chosen to promote any biol. effect, including angiogenesis inhibition, antitumor activity, and induction of apoptosis. The therapeutic effect may be achieved by direct administration of the **chimeric polypeptide**, or by transfecting cells with a vector including a nucleic acid encoding such a **chimeric polypeptide**.

AB The present invention encompasses fusion proteins of albumin with various therapeutic proteins. Therapeutic proteins may be stabilized to extend the shelf-life, and/or to retain the therapeutic protein's activity for extended periods of time in soln., in vitro and/or in vivo, by genetically or chem. fusing or conjugating the therapeutic protein to albumin or a fragment or variant of albumin. Use of albumin fusion proteins may also reduce the need to formulate the protein solns. with large excesses of carrier proteins to prevent loss of therapeutic proteins due to factors

such as binding to the container. Nucleic acid mols. encoding the albumin fusion proteins of the invention are also encompassed by the invention, as are vectors contg. these nucleic acids, host cells transformed with these nucleic acids vectors, and methods of making the albumin fusion proteins of the invention and using these nucleic acids, vectors, and/or host cells. Thus, plasmid vectors are constructed in which DNA encoding the desired therapeutic protein may be inserted for expression of the albumin fusion proteins in yeast (pPPC0005) and mammalian cells (pC4:HSA). Yeast-derived signal sequences from Saccharomyces cerevisiae invertase SUC2 gene, or the stanniocalcin or native human **serum albumin** signal peptides, are used for secretion in yeast or mammalian systems, resp. Thus, the fusion product of human growth hormone with residues 1-387 of human **serum albumin** retains essentially intact biol. activity after 5 wk of incubation in tissue culture media at 37.degree., whereas recombinant human growth hormone used as control lost its biol. activity in the first week. Although the potency of the albumin fusion proteins is slightly lower than the unfused counterparts in rapid bioassays, their biol. stability results in much higher biol. activity in the longer term in vitro assay or in vivo assays. Addnl., the present invention encompasses pharmaceutical compns. comprising albumin fusion proteins and methods of treating, preventing, or ameliorating diseases, disorders or conditions using albumin fusion proteins of the invention.

AB The prodn. performance of avians is enhanced by administering a heterologous fusion protein comprised of inhibin, or a fragment thereof, and a carrier protein. A DNA fragment (cINA521) was excised from the chicken inhibit .alpha.-subunit cDNA clone cINA6 using PstI digestion and cloned in the com. plasmid vector pMAL-c in frame with the maltose-binding protein (MBP) and a fusion protein of appropriate size was detected after IPTG induction and SDS-PAGE. The resulting protein conjugate (MBP-cINA521) was used as an antigen to immunize pre-pubescent, female Japanese quail (Coturnix coturnix japonica) against circulating inhibin levels. MBP-cINA521 immunization enhances prodn. performance as it accelerates the onset of puberty, increases egg lay intensity, and accelerates the onset of max. egg lay in Japanese quail. Improved prodn. performance is also obsd. in ostrich, emu, chicken, turkey, and parrots.

AB A conjugate between a target-seeking moiety and a modified superantigen, characterized in that the superantigen is a wild-type superantigen (**SA** I) in which an amino acid residue in a superantigen region (region I) detg. binding to TCR, preferably TCR V.beta., and T cell activation have been replaced by another amino acid residue while retaining the ability to activate a subset of T cells. In a preferred embodiment the modified superantigen is a chimer between at least two wild-type superantigens (**SA** I, **SA** II etc.) characterized in that one or more amino acid residues in a region detg. binding to TCR and T cell activation have been interchanged between various wild-type superantigens. A therapeutic method making use of modified/chimeric superantigens as defined in the preceding paragraphs. An antibody prepn. in which the **cysteine** residues that provide for interchain disulfide bonds have been mutated so as to forbid interchain disulfide bridges, preferably to serine residues, for use as a pharmaceutical. Plasmid 5T4Fab-SEA encoding fusion protein contg. antibody 5T4 variable region and murine IgG1 V.kappa. chain and Staphylococcal enterotoxin A was constructed, and the expressed chimeric superantigen was tested.

AB Some **cysteine**-contg. proteins upon sulfitolysis have been found to show anomalously retarded SDS-PAGE mobilities in non-reducing gels. These proteins include bovine **serum albumin**, ovalbumin, aldolase, RNase and a recombinant fusion protein (XA) consisting of a portion of .gamma.-interferon linked to the A chain of human insulin. This mobility shift has been employed to det. the stability of the sulfonated products and to study the kinetics of the sulfitolysis reaction. Partially sulfonated products of intermediate shifts were obsd. at 0.01% .beta.-mercaptoethanol (.beta.-ME), while 0.05% .beta.-ME gave a shift characteristic of the completely reduced protein. The undiluted sulfitolysis reagent reacted with XA to give within 1 min a gel shift characteristic of the fully sulfitolyzed protein. Its transition stages could be visualized at 15, 30 and 60 min when the reagent was dild. four-fold. In the presence of 8 M urea, the sulfitolysis of BSA was nearly complete at 30 min when the sulfitolysis reagent was used at a diln. of 1:5. However, under the same conditions BSA was predominantly unsulfitolyzed in the absence of urea. In order to elucidate the mechanism of sulfonation shift, several derivs. of XA, e.g. performic acid oxidized, alkylated with (a) iodoacetamide and (b) iodoacetate, have been prepd. While the mobility of XASSO3- was sensitive to the presence of .beta.-ME, all other derivs. moved in a .beta.-ME-insensitive fashion. Furthermore, while the nonreducing mobilities of the acidic derivs. (-SSO3-, -SO3- and -SCH2CO2-) were anomalously retarded and identical, the mobility of the iodoacetamide deriv. was intermediate between the retarded acidic derivs. above and XA below. These studies have suggested a role of the extended conformation of the A chain of insulin in causing a mobility shift of the acidic derivs. in this series. Similar results were obsd. in an analogous series of derivs. prepd. from BSA. Non-denaturing gel filtration analyses of native vs. sulfitolyzed samples of **serum albumin**, ovalbumin and RNase have indicated that the sulfitolyzed proteins elute earlier than their native counterparts and appear to be significantly larger than their true mol. wts. CD anal. has indicated significant loss in helicity of sulfitolyzed BSA. This suggests that the retarded mobility of sulfitolyzed proteins seen on SDS-PAGE is likely to be due to an expansion in the hydrodynamic vols. of these proteins, a phenomenon triggered by cleavage of disulfide bonds and further accentuated by the introduction of strongly neg. charged sulfonates.

AB Prodn. and secretion of a **heterologous protein** in a plant or plant cell is made possible by substituting a signal sequence functional in the plant host for the natural signal sequence immediately preceding the protein gene in the expression cassette introduced into the plant host. Thus, cloned cDNA for human prepro-**serum albumin** was manipulated to insert a sequence coding for a signal peptide from Samsun NN tobacco protein PROB12 immediately prior to the sequence coding for mature human **serum albumin**. Plasmid pMOG236, an Agrobacterium tumefaciens binary vector contg. this construct, was used to transform potato slices which were regenerated to mature transgenic plants. Leaves, stems, and tubers of these plants contained human **serum albumin**. The albumin was secreted by leaf cells and was found at elevated concn. in the extracellular fluid.

AB Human **serum albumin** fragments contg. the multiple sites for binding pharmaceuticals but not the C-terminal **cysteine** residues and the N-terminal long chain fatty acids binding sites are manufd. with recombinant Escherichia coli as carrier. Alternatively, the **serum albumin** fragments are manufd. as fusion products, esp. with the signal peptide of alk. phosphatase (phoA). Plasmid encoding a fusion protein of human **serum albumin** fragment (Met123-Pro303) and phoA signal peptide was constructed and transformed into E. coli. The E. coli transformants produced the fusion protein having a mol. wt. of 21000 (by SDSPAGE).

AB The invention provides nucleic acid segments of the human genome, particularly nucleic acid segments from genes including polymorphic sites. The polymorphisms were identified by resequencing of target sequences from individuals of diverse ethnic and geog. backgrounds by hybridization to probes immobilized to microfabricated arrays. Some of the single nucleotide polymorphisms (SNPs) specify a different amino acid sequence, some are silent or are in noncoding regions, and some specify a stop signal in protein translation. Allele-specific primers and probes hybridizing to regions flanking or contg. these sites are also provided. The nucleic acids, primers and probes are used in applications such as phenotype correlations, forensics, paternity testing, medicine and genetic anal.

AB Advanced glycation end product (AGE) activation of the signal-transducing receptor for AGE (RAGE) has been linked to a proinflammatory phenotypic

change within cells. However, the precise intracellular signaling pathways involved have not been elucidated. We demonstrate here that human **serum albumin** modified with N.epsilon.-(carboxymethyl)lysine (CML), a major AGE adduct that progressively accumulates with aging, diabetes, and renal failure, induced nuclear factor (NF)-.kappa.B-driven reporter gene expression in human monocytic THP-1 cells. The NF-.kappa.B response was blocked with a synthetic peptide corresponding to the putative ligand-binding domain of RAGE, with anti-RAGE antiserum, and by coexpression of truncated receptors lacking the intracellular domain. Signal transduction from RAGE to NF-.kappa.B involved the generation of reactive oxygen species, since reporter gene expression was blocked with the antioxidant N-acetyl-L-**cysteine**. CML-modified albumin produced rapid transient activation of tyrosine phosphorylation, extracellular signal-regulated kinase 1 and 2, and p38 mitogen-activated protein kinase (MAPK), but not c-Jun NH2-terminal kinase. RAGE-mediated NF-.kappa.B activation was suppressed by the selective p38 MAPK inhibitor SB203580 and by coexpression of a kinase-dead p38 dominant-neg. mutant. Activation of NF-.kappa.B by CML-modified albumin increased secretion of proinflammatory cytokines (tumor necrosis factor-.alpha., interleukin-1.beta., and monocyte chemoattractant protein-1) severalfold, and inhibition of p38 MAPK blocked these increases. These results indicate that p38 MAPK activation mediates RAGE-induced NF-.kappa.B-dependent secretion of proinflammatory cytokines and suggest that accelerated inflammation may be a consequence of cellular activation induced by this receptor.

AB Arginine-L-**cysteine** dipeptide adsorbates are used in this study as a model system for **G-protein**-coupled **receptors** (GPCRs). An arginine-contg. model mol. is chosen because the GPCR .alpha.2A has been shown to include an arginine-rich region in the G-protein-binding part of the third intracellular loop, and the role of arginines by means of recognition is believed to exceed their pos. charge. The dipeptide Arg-Cys is adsorbed to gold surfaces and the peptide monolayers are characterized. These peptide monolayers are then used for G-protein adsorption expts. to study the mol. interaction and binding. The mol. adsorption, orientation, and chem. binding of the peptide to the surface are studied by XPS and IR reflection-absorption spectroscopy. A chem. shift in the S(2p) core level spectrum of the

peptide adsorbate on gold shows that there is a strong mol. surface interaction consistent with a chem. binding of the peptide to the surface through the sulfur atom. With the **cysteine** part linked to the surface, the arginine part of the mol. is available for further adsorption processes. Monolayers of Arg-Cys, L-**cysteine**, and cysteamine are used for G-protein adsorption expts. Adsorption of human **serum albumin** and human Igs on the same monolayers are studied for comparison. The anal. tool is surface plasmon resonance. Two different buffers are used for the adsorption studies, and the influence of buffer compn. on protein adsorption is discussed.

AB There is considerable evidence that significant factor underlying the individual variability in response to disease, therapy and prognosis lies in a person's genetic make-up. There have been numerous examples relating that polymorphisms within a given gene can alter the functionality of the protein encoded by that gene thus leading to a variable physiol. response. In order to bring about the integration of genomics into medical practice and enable design and building of a technol. platform which will enable the everyday practice of mol. medicine a way must be invented for the DNA sequence data to be aligned with the identification of genes central to the induction, development, progression and outcome of disease or physiol. states of interest. According to the invention, the no. of genes and their configurations (mutations and polymorphisms) needed to be identified in order to provide crit. clin. information concerning individual prognosis is considerably less than the 100,000 thought to comprise the human genome. The identification of the identity of the core group of genes enables the invention of a design for genetic profiling technologies which comprises of the identification of the core group of genes and their sequence variants required to provide a broad base of clin. prognostic information - "genostics". The "Genostic.RTM." profiling of patients and persons will radically enhance the ability of clinicians, healthcare professionals and other parties to plan and manage healthcare provision and the targeting of appropriate healthcare resources to those deemed most in need. The use of this invention could also lead to a host of new applications for such profiling technologies, such as identification of persons with particular work or environment related risk, selection of applicants for employment, training or specific opportunities or for the enhancing of the planning and organization of health services, education services and social services.

AB A method for development of proteins with new combinations of properties by recursive recombination of coding sequences of different origins and screening of gene products for desired properties is described. Recombination can be in vitro, or in vivo, e.g. using the cre/loxP system. Further variation can be introduced using mutagenesis-prone methods such as DNA repair. One method is denaturing and renaturing a population of fragments of 20-100 base pairs and selecting for those hybrids with base pair mismatches. These mismatched sequences are then ligated together to generate new sequences that will undergo DNA repair-mediated mutation. The method is flexible enough to allow coarse, or large scale, changes in sequences or it can be used at a very fine level: generating changes in a small subsequence. Many screening procedures may be used, but they must be carefully designed to detect changes of interest. Novel variants of calf intestinal alk. phosphatase with novel substrate specificity, human .alpha. interferon with higher specific activity, and luciferases with

increased stability are generated.

AB The expression vector of **endostatin** gene was constructed and its transfection into C6 cell and its antiangiogenesis activity were studied. The rat **serum albumin** secretive signal was linked to the **endostatin** gene C terminal by PCR, this fused gene was then inserted into polylinker sites of eukaryotic expression vector pcDNA3 to construct pcDNA-SE. The vector was transfected into C6 glioma cells by lipofectamine and the pos. clone was screened by G418. The activity of **endostatin** protein expressed by the C6 cells was examd. by immunohistochem. and the **cell proliferation** assay. The eukaryotic expression vector pcDNA-SE was successfully constructed and transfected into C6 cells. The cells expressed the **endostatin** protein which could inhibit the endotheliocyte proliferation. **Endostatin** was a potent **angiogenesis** inhibitor. The expt. led a foundation for following expts. on antiangiogenesis gene therapy of **tumors**.

AB **Tumor** growth requires **angiogenesis**, which in turn requires an imbalance in the presence of angiogenic and **angiostatic** factors. We have shown that the CXC chemokine family, consisting of members that are either angiogenic or **angiostatic**, is a major determinant of **tumor**-derived **angiogenesis** in non-small-cell lung **cancer** (NSCLC). **Intratumor** injection of interferon-inducible protein 10 (IP-10, or CXCL10), an **angiostatic** CXC chemokine, led to reduced **tumor** growth in a SCID mouse model of NSCLC. In this study, we hypothesized that treatment with CXCL10 would, by restoring the **angiostatic** balance, improve long-term survival in NSCLC-bearing SCID mice. To test this hypothesis, A549 NSCLC cells were injected in the subcutis of the flank, followed by **intratumor** injections with CXCL10 continuously (group I), or for ten weeks (group II), or a control group (human **serum albumin**). Median survival was 169, 130, and 86 days resp. ($P < 0.0001$). We extended these studies to examine the mechanism of prolonged survival in CXCL10-treated mice. CXCL10 treatment inhibited lung **metastases**, but was dependent upon continued treatment, and was assocd. with an increased rate of **apoptosis**

in the primary **tumor**, with no direct effect on the proliferation of the NSCLC cells. Furthermore, the inhibition of lung **metastases** was due to the **angiostatic** effect of CXCL10 on the primary **tumor**, since the rate of **apoptosis** within lung **metastases** was unaffected. These data suggest that anti-angiogenic therapy of human lung **cancer** should be continued indefinitely to realize persistent benefit, and confirms the anti-**metastatic** capacity of localized **angiostatic** therapy.

AB Amifostine was investigated for its ability to inhibit spontaneous **metastases** formation using the well-characterized murine **sarcoma**, **Sa**-NH. Amifostine was administered i.p. at a dose of 50 mg/kg every other day for 6 days to C3Hf/Kam mice until **tumors** reached an av. size of 8-8.5 mm in diam. Amifostine was again administered immediately after surgical removal of the **tumor**-bearing limbs by amputation, and then once more 2 days later. Twenty-one days later, animals were evaluated for the presence of spontaneously developed pulmonary **metastases**. **Nontumor**-bearing control animals were sham treated using the same dosing and surgery schedules. Treatment with amifostine appeared to slightly delay **tumor** growth, i.e., 13 vs. 12 days for **tumors** to reach an av. diam. of 8 mm. Amifostine reduced both the incidence of pulmonary **metastases** formed in exptl. animals from 77% to 57% ($p < 0.05$), and their av. no. per animal from 12.8 .+-. 5.4 (SEM) to 2.9 .+-. 1.1 (SEM). The effect of amifostine exposure on serum levels of the **angiogenesis** inhibitor **angiostatin** was also detd. using Western blot anal. Consistent with the **antimetastatic** effect, exposure of animals to 50 mg/kg of amifostine resulted in a 4-fold enhanced serum level of **angiostatin** above control levels. This phenomenon occurred in **tumor**-bearing and **nontumor**-bearing animals. The effects of amifostine on matrix metalloproteinase (MMP) enzymic activity was also detd. using gelatin zymog. Conditioned growth medium collected from **Sa**-NH cells grown to confluency was exposed to various concns. of SH, i.e., 2-[(aminopropyl)amino]ethane-thiol (WR-1065), the active thiol form of amifostine, for either 30 min or 18 h. WR-1065, as a function of increasing dose and time, inhibited the enzymic activities of MMP-2 and MMP-9. At a concn. and time of exposure likely to be achieved in vivo, i.e., 40 .mu.M and 30 min, MMP-2 and MMP-9 activities were reduced to between 30% and 40% of control values. Consistent with these affects, WR-1065 was also found to be effective in inhibiting the ability of **Sa**-NH cells to migrate through Matrigel membranes.

After an 18-h exposure under in vitro conditions, WR-1065 at concns. of 4, 40 and 400 .mu.M, and 4 mM, inhibited **Sa**-NH migration to 11%, 44%, 81% and 97% of control values, resp. The abilities of amifostine and its active thiol WR-1065 to stimulate **angiostatin** prodn. in mice, and to inhibit the MMP enzymic activities and invasion ability of **Sa**-NH cells under in vitro conditions, are consistent with the obsd. **antimetastatic** effects exhibited against **Sa**-NH **tumors** growing in vivo.

AB Although the mature neutrophil is one of the better characterized mammalian cell types, the mechanisms of myeloid differentiation are incompletely understood at the mol. level. A mouse promyelocytic cell line (MPRO), derived from murine bone marrow cells and arrested developmentally by a dominant-neg. retinoic acid receptor, morphol. differentiates to mature neutrophils in the presence of 10.mu.M retinoic acid. An extensive catalog was prepd. of the gene expression changes that occur during morphol. maturation. To do this, 3'-end differential display, oligonucleotide chip array hybridization, and 2-dimensional protein electrophoresis were used. A large no. of genes whose mRNA levels are modulated during differentiation of MPRO cells were identified. The results suggest the involvement of several transcription regulatory factors not previously implicated in this process, but they also emphasize the importance of events other than the prodn. of new transcription factors. Furthermore, gene expression patterns were compared at the level of mRNA and protein, and the correlation between 2 parameters was studied.

AB The authors used cDNA microarrays contg. 3000 different rat genes to study the consequences of severe hormonal deficiency (hypophysectomy) on the gene expression patterns in heart, liver, and kidney. Hybridization signals were seen from a majority of the arrayed cDNAs; nonetheless, tissue-specific expression patterns could be delineated. Hypophysectomy affected the expression of genes involved in a variety of cellular functions. Between 16-29% of the detected transcripts from each tissue changed expression level as a reaction to this condition. Chronic treatment of hypophysectomized animals with human GH also caused significant changes in gene expression patterns. The study confirms previous knowledge concerning certain gene expression changes in the above-mentioned situations and provides new information regarding hypophysectomy and chronic human GH effects in the rat. Furthermore, the authors have identified several new genes that respond to GH treatment. The results represent a first step toward a more global understanding of gene expression changes in states of hormonal deficiency.

AB To research anti-**angiogenesis** activity of, human AK(1-3)[**angiostatin** kringle(1-3)], rat **serum albumin** signal dipeptide was transfected into C6 cell utilizing lipofectamine. Electron microscope, flow cytometry, immunohistochem. and Western blot were used to detect the ultramicrostructure, cell cycle and expression of AK(1-3) of C6 cell transfected and untransfected. The anti-**angiogenesis** activity of AK(1-3) expressed by C6 cell was identified with human umbilical vein endothelial **cell proliferation** assay. The results indicate that C6 cell successfully transfected with AK(1-3) gene can stably express active AK(1-3) which potently inhibits endothelial **cell proliferation**. The study provides a promise for the anti-**angiogenesis** gene therapy in vivo.

AB The methods and compns. of the present invention are directed to enhancing an immune response and increasing vaccine efficacy through the simultaneous or sequential targeting of specific immune system components. More particularly, specific immune components, such as macrophages, dendritic cells, B cells and T cells, are individually activated by component-specific immunostimulating agents. One such component-specific immunostimulating agent is an antigen-specific, species-specific monoclonal antibody. The invention is also directed to a method for the in vitro prodn. of the antigen-specific, species-specific monoclonal antibodies which relies upon the in vitro conversion of blood-borne immune cells, such as macrophages and lymphocytes. Vaccine efficacy is enhanced by the administration of compns. contg. component-specific immunostimulating agents and other elements, such as antigens or carrier particles, such as colloidal methods, such as gold.

AB As demonstrated by a simple procedure based on indirect immunopptn., proteins retained on heparin-Sepharose 4B from postmitochondrial supernatants of rat liver and Zajdela hepatoma catalyze the translation of rabbit **serum albumin** mRNA in the presence of ribosomal subunits from rat liver, Zajdela hepatoma, or rabbit reticulocytes. The albumin synthesis shows an optimum at 1.5 mM MgCl2 and 25 mM KCl and requires ATP and GTP. It is significantly stimulated by tRNA and proceeds for >2 h, suggesting a high rate of reinitiation. At the optimum

ribosome:mRNA ratio of 13:1, the immunoprecipitable radioactivity was >15-20-fold the blank values. Fluorog. of polyacrylamide slabs after electrophoresis of immunoppts. revealed the presence of only complete full-size **serum albumin** without any smaller peptides resulting from premature terminations of polypeptide chains, demonstrating faithful translation. In stained gels only, both heavy and light chains of IgG were found, indicating that the assay procedure is highly specific and reliable. The fractionated **heterologous protein** -synthesizing system described in this paper may be generally useful for studies of the synthesis of specific proteins and factors affecting their rates since, unlike comparable translation assays, a precise calcn. of the balance of newly synthesized proteins is possible.

AB Antibodies elicited in rabbits by immunization with conjugates prepd. from serum albumins and nitrogen mustard derivs. of quinacrine (atebrin) had strong binding sites complementary to the quinacrine hapten. The characteristic absorption spectrum of quinacrine made possible accurate detns. of the antigen-antibody compn. of the serol. ppts. Conclusive evidence that such antibodies, in addn. to reacting with the quinacrine component of **heterologous protein** test conjugates, bind quinacrine itself, as well as closely related acridine haptens, was provided by quant. inhibition studies. Atebrin and the hydroxy precursors of several heterocyclic nitrogen mustards caused more than a 50% inhibition of the antigen-antibody reactions. The antibodies elicited by the quinacrine-protein conjugates in ascites **tumor**-bearing mice substantially neutralized the **antitumor** effectiveness of the low dosages (0.5-2.0 .mu.mol/kg) of the acridine nitrogen mustards that were required for a demonstration of chemotherapeutic activity. In contrast, nitrogen mustard, which has no quinacrine moiety, was not affected. Immunization with unaltered **serum albumin** had no influence on the activity of the acridine nitrogen mustards. Quant. in vitro inhibition studies allowed satisfactory predictions of in vivo immunol. reactivity.

AB Antibodies toward 9,10-dimethyl-1,2-benzanthryl-3-carbamido-horse **serum albumin** conjugate reacted well with **heterologous proteins** contg. haptens which were either similar in size and configuration (3,4-benzopyrene) or smaller (1,2-benzanthracene, 2-acetylaminofluorene), but poorly with those contg. a larger structure (1,2,5,6-dibenzanthracene). The structural alteration produced by photooxidation of 9,10-dimethyl-1,2-benzanthracene was reflected by a change in haptenic activity. Conjugates in which 2'-methyl-4-dimethylaminostilbene was joined to protein by an azo or carbamido linkage showed haptenic activity and cross reactivity, but the 2 linkages were not equiv. The terminal dimethylaminophenyl portion of the substituted stilbene mol. was of serologic importance. After exhaustive sepn. of the antihapten-protein serum by native protein and by hapten-**heterologous protein**, there remained much antibody which was specifically pptd. by the completely homologous test antigen.
